SAMPLE

Gaussian Noise

1 Overview

- 1.1 Location \$(AMDAPPDKSAMPLESROOT)\samples\opencl\cpp_cl\app
- 1.2 How to Run See the Getting Started guide for how to build samples. You first must compile the sample.

Use the command line to change to the directory where the executable is located. The precompiled sample executable is at $(AMDAPPDKSAMPLESROOT) \\samples \\opencl \\bin \\x86_64 \\for 64-bit builds.$

Type the following command(s).

- GaussianNoise This generates Gaussian noise in the input image.
- 2. GaussianNoise -h This prints the help file.

1.3 Command Table 1 lists, and briefly describes, the command line options. Line Options

Table 1	Command Line Options	
Short Form	Long Form	Description
-h	help	Shows all command options and their respective meaning.
	device	Devices on which the program is to be run. Acceptable values are cpu or gpu.
-d	quiet	Quiet mode. Suppresses all text output.
-е	verify	Verify results against reference implementation.
-t	timing	Print timing.
	dump	Dump binary image for all devices.
	load	Load binary image and execute on device.
	flags	Specify compiler flags to build kernel.
-р	platformId	Select platformId to be used (0 to N-1, where N is the number of available platforms).
-d	deviceId	Select deviceld to be used (0 to N-1, where N is the number of available devices).
-v	version	AMD APP SDK version string.
-i	iterations	Number of iterations for kernel execution.
-f	factor	Noise factor.

2 Introduction

Gaussian noise is statistical noise that has a probability density function of the normal distribution (also known as Gaussian distribution). The values that the noise can take on are Gaussian-distributed.

This sample takes an input image and generates a Gaussian deviation by using the pixel value as a seed. This deviation is then added to all the components of the pixel.

3 Implementation Details

Each thread generates two uniform random numbers in the range (0, 1), using a linear congruential generator function.

A minimal standard linear congruential generator proposed by Park and Miller (see reference [1]) is:

 $I_i + 1 = a I_i \mod m$

where a = 16807 (7⁵), and m = $2^{31} - 1$.

To implement this, we use Schrage's method (see reference [2]), which is based on an approximate factorization of m.

m = aq + r, that is: q = [m/a], $r = m \mod a$

We then apply a shuffling algorithm by Bays and Durham, as described in Knuth (see reference [3]), to remove low-order serial correlations.

A Box-Muller transform is then applied to obtain the numbers in the Gaussian distribution. This takes two uniform samples, u_0 and u_1 , and transforms them into two Gaussian distributed samples, r_0 and r_1 , using the following relations.

$$r_0 = \sin(2\pi u_0)\sqrt{-2\log(u_1)},$$

$$r_1 = \cos(2\pi u_0)\sqrt{-2\log(u_1)}.$$

This method, which is the simple version of this transform, is suitable for GPUs because it is mathematically intensive and free of loops and branches.

Another version of this transform, called the Polar form, relies on looping, which is less efficient on GPUs. The Polar form uses rejection to discard numbers, as shown in the following code sample.

Using this form results in reduced performance compared to the simple (Box-Muller) version.
